1. Introduction

The term "Automata" is derived from the Greek word "αὐτόµατα" which means "self-acting". An automaton (Automata in plural) is an abstract self-propelled computing device which follows a predetermined sequence of operations automatically.

An automaton with a finite number of states is called a **Finite Automaton (FA)** or **Finite State Machine (FSM)**.

2. Why to study Theory of Computation?

Theory of computation is mainly concerned with the study of how problems can be solved using algorithms. It is the study of mathematical properties both of problems and of algorithms for solving problems that depend on neither the details of today's technology nor the programming language.

It is still useful in two key ways:

- It provides a set of *abstract structures* that are useful for solving certain classes of problems. These abstract structures can be implemented on whatever hardware/software platform is available.
- It defines provable limits to what can be computed regardless of processor speed or memory size. An understanding of these limits helps us to focus our design effort in areas in which it can pay off, rather than on the computing equivalent of the search for a perpetual motion machine.

The goal is to discover fundamental properties of the problems like:

- Is there any computational *solution* to the problem? If not, is there a restricted but useful variation of the problem for which a solution does exist?
- If a solution exists, can it be implemented using some fixed amount of memory?
- If a solution exists, how efficient is it? More specifically, how do its time and space requirements grow as the size of the problem grows?
- Are there groups of problems that are equivalent in the sense that if there is an efficient solution to one member of the group there is an efficient solution to all the others?

Applications of theory of computation:

- **Development of Machine Languages**: Enables both machine-machine and person-machine communication. Without them, none of today's applications of computing could exist. Example: Network communication protocols, HTML etc.
- **Development of modern programming languages**: Both the design and the implementation of modern programming languages rely heavily on the theory of context-free languages. Context-free grammars are used to document the languages syntax and they form the basis for the parsing techniques that all compilers use.
- **Natural language processing**: It is a field of computer science, artificial intelligence, and computational linguistics concerned with the interactions between computers and human (natural) languages.
- **Automated hardware systems:** Systems as diverse as parity checkers, vending machines, communication protocols, and building security devices can be straightforwardly described as finite state machines, which is a part of theory of computation.

- **Video Games:** Many interactive video games are use large nondeterministic finite state machines.

- **Security** is perhaps the most important property of many computer systems. The undecidability results of computation show that there cannot exist a general-purpose method for automatically verifying arbitrary security properties of programs.

- **Artificial intelligence:** Artificial intelligence programs solve problems in task domains ranging from medical diagnosis to factory scheduling. Various logical frameworks have been proposed for representing and reasoning with the knowledge that such programs exploit.

- **Graph Algorithms:** Many natural structures, including ones as different as organic molecules and computer networks can be modeled as graphs. The theory of complexity tells us that, is there exist efficient algorithms for answering some important questions about graphs. Some questions are "hard", in the sense that no efficient algorithm for them is known nor is one likely to be developed.

### 3. Strings

**Alphabet**

*Definition:* An alphabet is any finite set of symbols denoted by $\Sigma$ (Sometimes also called as characters or symbols).

*Example:* $\Sigma = \{a, b, c, d\}$ is an alphabet set where ‘a’, ‘b’, ‘c’, and ‘d’ are symbols.

**String**

*Definition:* A string is a finite sequence of symbols taken from $\Sigma$.

*Example:* ‘cabcad’ is a valid string on the alphabet set $\Sigma = \{a, b, c, d\}$

<table>
<thead>
<tr>
<th>Alphabet name</th>

<td>A music alphabet</td>
<td>{$\circ$, $\cdot$, $\circ$, $\cdot$}</td>
<td>$\varepsilon$, 00...01</td>
</tr>
</tbody>
</table>

### 3.1. Functions on Strings

**Length of a String**

Definition: It is the number of symbols present in a string. (Denoted by $|.|$).

Examples: If $s = \text{‘cabcad’}$, $|s| = 6$; Also $|11001101| = 7$

If $|s| = 0$, it is called an empty string, denoted by $\varepsilon$. $|\varepsilon| = 0$
Concatenation of strings: The concatenation of two strings $s$ and $t$, written $s||t$ or simply $st$, is the string formed by appending $t$ to $s$. For example, if $x = \text{good}$ and $y = \text{bye}$, then $xy = \text{goodbye}$. So $|xy| = |x| + |y|$.

The empty string, $e$, is the identity for concatenation of strings. ($xe = ex = x$).

Concatenation, as a function defined on strings is associative. $(st)w = s (tw)$.

String Replication

For each string $w$ and each natural number $i$, the string $w^i$ is defined as:

Example: $a^3 = aaa$, $(\text{bye})^2 = \text{byebye}$, $a^0b^3 = bbb$

String Reversal: For each string $w$, the reverse of $w$, written as $w^R$, is defined as:

If $|w| = 0$ then $w^R = w = e$.
If $|w| \geq 1$ then $\exists a \in \Sigma (\exists u \in \Sigma^* (w = ua))$, (i.e., the last character of $w$ is $a$.) Then define $w^R = au^R$.

Theorem: If $w$ and $x$ are strings, then $(wx)^R = x^Rw^R$.

For example, $(\text{name}tag)^R = (\text{tag})^R(\text{name})^R = \text{gateman}$.

Proof: The proof is by induction on $|x|$:

Base case: $|x| = 0$. Then $x = e$, and $(wx)^R = (we)^R = (w)^R = (\epsilon)^R = \epsilon^Rw^R = x^Rw^R$.

Prove: $\forall n \geq 0 (((|x| = n) \rightarrow ((wx)^R = x^Rw^R)) \rightarrow (((|x| = n + 1) \rightarrow ((wx)^R = x^Rw^R))))$.

Consider any string $x$, where $|x| = n + 1$. Then $x = ua$ for some character $a$ and $|u| = n$. So:

$$(wx)^R = (w(ua))^R$$

rewrite $x$ as $ua$

$$(w(ua))^R = ((w(ua))^R$$

associativity of concatenation

$$(w(ua))^R = a(ua)^R$$

definition of reversal

$$(a(ua)^R) = a(u(aw))^R$$

induction hypothesis

$$(u(aw))^R = (aw)^Rw^R$$

associativity of concatenation

$$(aw)^Rw^R = (ua)^Rw^R$$

definition of reversal

$$(x^Rw^R = x^Rw^R$$

rewrite $ua$ as $x$

3.2. Relations on strings

Substring: A string $s$ is a substring of a string $t$ iff $s$ occurs contiguously as part of $t$

For example: $\text{aaa}$ is a substring of $\text{aaabbb}a\text{aa}$, $\text{aaaaa}$ is not a substring of $\text{aaabbb}a\text{aa}$

Proper Substring: A string $r$ is a proper substring of a string $t$, iff $t$ is a substring of $t$ and $s \neq t$. Every string is a substring (although not a proper substring) of itself. The empty string, $\epsilon$, is a substring of every string.

Prefix: A string $s$ is a prefix of $t$, iff $\exists x \in \Sigma^* (t = sx)$. A string $s$ is a proper prefix of a string $t$ iff $s$ is a prefix of $t$ and $s \neq t$. Every string is a prefix (although not a proper prefix) of itself. The empty string $\epsilon$, is a prefix of every string. For example. the prefixes of abba are: $\epsilon$, $a$, $ab$, abb, abba.
**Suffix**: A string \( s \) is a suffix of \( t \), iff \( \exists x \in \Sigma^* (t = xs) \). A string \( s \) is a proper suffix of a string \( t \) iff \( s \) is a suffix of \( t \) and \( s \neq t \). Every string is a suffix (although not a proper suffix) of itself. The empty string \( \epsilon \), is a suffix of every string. For example, the prefixes of \( abba \) are: \( \epsilon, \ a, \ ba, \ bba, \ abba \).

### 4. Languages

A language is a (finite or infinite) set of strings over a finite alphabet \( \Sigma \). When we are talking about more than one language, we will use the notation \( \Sigma_L \), to mean the alphabet from which the strings in the language \( L \) are formed.

Let \( \Sigma = \{a, b\} \). \( \Sigma^* = \{ \epsilon, a, b, aa, ab, ba, bb, aaa, aab ... \} \).

Some examples of languages over \( \Sigma \) are:

- \( \Phi \), \( \{\epsilon\} \), \( \{a, b\} \), \( \{\epsilon, a, aa, aaa, aaaa, aaaaa\} \), \( \{\epsilon, a, aa, aaa, aaaaa, ... \} \).

### 4.1. Techniques for Defining Languages

There are many ways. Since languages are sets, we can define them using any of the set-defining techniques.

**Ex-1**: *All a's Precede All b's*,

\( L = \{w \in \{a,b\}*: \text{an a's precede all b's in } w\} \). The strings \( \epsilon, a, aa, aabbb, \) and \( bb \) are in \( L \). The strings \( aba, ba, \) and \( abc \) are not in \( L \).

**Ex-2**: *Strings that end in ‘a’*

\( L = \{x: \exists y \in \{a, b\}*, (x = ya)\} \). The strings \( a, aa, aaa, bbaa \) and \( ba \) are in \( L \). The strings \( \epsilon, bab, \) and \( bca \) are not in \( L \). \( L \) consists of all strings that can be formed by taking some string in \( \{a, b\}\) and concatenating a single \( a \) onto the end of it.

**Ex-3**: *Empty language*

\( L = \{\} = \Phi \), the language that contains no strings. *Note*: \( L = \{\epsilon\} \) the language that contains a single string, \( \epsilon \). Note that \( L \) is different from \( \Phi \).

**Ex-4**: *Strings of all ‘a’ s containing zero or more ‘a’s*

Let \( L = \{ a^n: n \geq 0 \} \). \( L = (\epsilon, a, aa, aaa, aaaaa, ... ) \)

**Ex-5**: We define the following languages in terms of the prefix relation on strings:

- \( L_1 = \{wc(a, b)^*: \text{no prefix of } w \text{ contains } b\} = \{ e, a, aa, aaa, aaaaa, aaaaaa, ... \} \).
- \( L_2 = \{wc(a, b)^*: \text{no prefix of } w \text{ starts with } b\} = \{w \in \{a, b\}*: \text{the first character of } w \text{ is } a\} \cup \{\epsilon\} \).
- \( L_3 = \{wc(a, b)^*: \text{every prefix of } w \text{ starts with } b\} = \Phi \). \( L_3 \) is equal to \( \Phi \) because \( \epsilon \) is a prefix of every string. Since \( \epsilon \) does not start with \( b \), no strings meet \( L_3 \)’s requirement.

Languages are sets. So, a computational definition of a language can be given in two ways;

- a **language generator**, which enumerates (lists) the elements of the language, or
- a **language recognizer**, which decides whether or not a candidate string is in the language and returns *True* if it is and *False* if it isn't.

For example, the logical definition. \( L = \{x: \exists y \epsilon \{a, b\}^* (x = ya)\} \) can be turned into either a language generator (enumerator) or a language recognizer.
In some cases, when considering an enumerator for a language, we may care about the order in which the elements of \( L \) are generated. If there exists a total order \( D \) of the elements of \( \Sigma_L \), then we can use \( D \) to define on \( L \) a total order called lexigraphic order (written \( <_{L} \)):

- Shorter strings precede longer ones: \( \forall x \, (\forall y \, ((|x| < |y|) \rightarrow (x <_{L} y))) \) and
- Of strings that are the same length sort them in dictionary order using \( D \).

Let \( L = \{ w \in \{a, b\}^*; \text{ all } a\text{'s precede all } b\text{'s}\} \). The lexicographic enumeration of \( L \): 
\[ \varepsilon, a, b, aa, ab, bb, aaa, aab, abb, bbb, aaaa, ... \]

### 4.2. Cardinality of a Language

- Cardinality refers to the number of strings in the language.
- The smallest language over any alphabet is \( \phi \), whose cardinality is 0.
- The largest language over any alphabet \( \Sigma \) is \( \Sigma^* \). Suppose that \( \Sigma = \phi \), then \( \Sigma^* = \{ \varepsilon \} \) and \( |\Sigma^*| = 1 \). In general, \( |\Sigma^*| \) is infinite.

**Theorem:** If \( \Sigma \neq \emptyset \) then \( \Sigma^* \) is countably infinite.

**Proof:** The elements of \( \Sigma^* \) can be lexicographically enumerated by a straightforward procedure that:
- Enumerates all strings of length 0, then length 1, then length 2, and so forth.
- Within the strings of a given length, enumerates them in dictionary order.

This enumeration is infinite since there is no longest string in \( \Sigma^* \). By Theorem A.1, since there exists an infinite enumeration of \( \Sigma^* \), it is countably infinite.

### 4.3. How Many languages are there?

Let \( \Sigma \) be an alphabet. The set of languages defined on \( \Sigma \) is \( P(\Sigma^*) \), the power set of \( \Sigma^* \), or the set of all subsets of \( \Sigma^* \).

If \( \Sigma = \emptyset \) then \( \Sigma^* = \{ \varepsilon \} \) and \( P(\Sigma^*) = \{ \emptyset, \{ \varepsilon \} \} \).

**Theorem:** If \( \Sigma \neq \emptyset \) then \( \Sigma^* \) is countably infinite.

**Proof:** The elements of \( \Sigma^* \) can be lexicographically enumerated by a straightforward procedure that:
- Enumerates all strings of length 0, then length 1, then length 2, and so forth.
- Within the strings of a given length, enumerates them in dictionary order.

This enumeration is infinite since there is no longest string in \( \Sigma^* \). By Theorem A.1, since there exists an infinite enumeration of \( \Sigma^* \), it is countably infinite.

### 4.4. Functions on Languages

Since languages are sets, all of the standard set operations are well-defined on languages. **Union**, **intersection**, **difference** and **complement** are quite useful.
Concatenation

Let \( L_1 \) and \( L_2 \) be two languages defined over some alphabet \( \Sigma \). Then their concatenation, written \( L_1L_2 \) is:

\[
L_1L_2 = \{ w \in \Sigma^* : \exists s \in L_1 (\exists t \in L_2 (w = st)) \}.
\]

Example: Let: \( L_1 = \{ \text{cat, dog, mouse, bird} \} \). \( L_2 = \{ \text{bone, food} \} \).
\( L_1L_2 = \{ \text{catbone, catfood, dogbone, dogfood, mousebone, mousefood, birdbone, birdfood} \} \).

The language \( \{ \epsilon \} \) is the identity for concatenation of languages. So for all languages \( L \),
\( L\{\epsilon\} = \{\epsilon\}L = L \).

The language \( \Phi \) is a zero for concatenation of languages. So, for all languages \( L \), \( L\Phi = \Phi L = \Phi \). That \( \Phi \) is a zero follows from the definition of the concatenation of two languages as the set consisting of all strings that can he formed by selecting some string ‘s’ from the first language and some string ‘t’ from the second language and then concatenating them together. There are no ways to select a string from the empty set.

**Concatenation** on languages is associative. So, for all languages \( L_1L_2 \) and \( L_3 \):

\[
(L_1L_2)L_3 = L_1 (L_2L_3) .
\]

Reverse

Let \( L \) be a language defined over some alphabet \( \Sigma \). Then the reverse of \( L \), written \( L^R \) is:

\[
L^R = \{ w \in \Sigma^* : w = x^R \text{ for some } x \in L \}.
\]

In other words, \( L^R \) is the set of strings that can be formed by taking some string in \( L \) and reversing it.

**Theorem:** If \( L_1 \) and \( L_2 \) are languages, then \( (L_1L_2)^R = L_2^R L_1^R \).

**Proof:** If \( x \) and \( y \) are strings, then \( \forall x (\forall y ((xy)^R = y^Rx^R)) \)

\[
(xy)^R = \{ y^R x^R : x \in L_1 \text{ and } y \in L_2 \}.
\]

For all \( x \in L_1 \) and \( y \in L_2 \):

\[
L_2^R L_1^R = \{ y^R x^R : x \in L_1 \text{ and } y \in L_2 \}.
\]
**Kleene Star**

Definition: The *Kleene star* denoted by $\Sigma^*$, is a unary operator on a set of symbols or strings, $\Sigma$, that gives the infinite set of all possible strings of all possible lengths over $\Sigma$ including $\epsilon$.

Representation: $\Sigma^* = \Sigma^0 \cup \Sigma^1 \cup \Sigma^2 \cup \ldots$ where $\Sigma^p$ is the set of all possible strings of length $p$.

Example: If $\Sigma = \{a, b\}$, $\Sigma^* = \{\lambda, a, b, aa, bb, \ldots\}$

**Kleene Closure / Plus**

Definition: The set $\Sigma^+$ is the infinite set of all possible strings of all possible lengths over $\Sigma$ excluding $\epsilon$. $\Sigma^+ = \Sigma^* - \{\epsilon\}$

Representation: $\Sigma^+ = \Sigma^1 \cup \Sigma^2 \cup \Sigma^3 \cup \ldots$

Example: If $\Sigma = \{a, b\}$, $\Sigma^+ = \{a, b, aa, bb, \ldots\}$

**Closure**: A set $S$ is closed under the operation @ if for every element $x \& y$ in $S$, $x@y$ is also an element of $S$.

4.5. A Language Hierarchy

A Machine-Based Hierarchy of Language Classes are shown in the diagram.

We have four language classes:

1. **Regular languages**, which can be accepted by some finite state machine.
2. **Context-free languages**, which can be accepted by some pushdown automaton.
3. **Decidable** (or simply D) languages, which can be decided by some Turing machine that always halts.
4. **Semi-decidable** (or SD) languages, which can be semi-decided by some Turing machine that halts on all strings in the language.

Each of these classes is a proper subset of the next class, as illustrated in the Figure. As we move outward in the language hierarchy, we have access to tools with greater and expressive power. We can define $A^nB^nC^n$ as a decidable language but not as a context-free or a regular one. These matters because expressiveness generally comes at a price. The price may be: Computational efficiency, decidability and clarity.

- **Computational efficiency**: Finite state machines run in time that is linear in the length of the input string. A general context-free parser based on the idea of a pushdown automaton requires time that grows as the cube of the length of the input string.
Turing machine may require time that grows exponentially (or faster) with the length of the input string.

- **Decidability**: There exist procedures to answer many useful questions about finite state machines. For example, does an FSM accept some particular string? Is an FSM minimal? Are two FSMs identical? A subset of those questions can be answered for pushdown automata. None of them can be answered for Turing machines.

- **Clarity**: There exist tools that enable designers to draw and analyze finite state machines. Every regular language can also be described using the regular expression pattern language. Every context-free language, in addition to being recognizable by some pushdown automaton, can be described with a context-free grammar.

### 5. Finite State Machines (FSM)

A **finite state machine** (or FSM) is a computational device whose input is a string and whose output is one of two values; Accept and Reject. FSMS are also sometimes called **finite state automata** or **FSAs**.

#### 5.1. Deterministic FSM

- We begin by defining the class of FSMS whose behavior is **deterministic**.
- These machines make exactly one move at each step.
- The move is determined by the current state and the next input character.

**Definition**: Deterministic Finite State Machine (DFSM) is \( M = (K, \Sigma, \delta, s, A) \), where:

- \( K \) is a finite set of states
- \( \Sigma \) is an alphabet
- \( s \in K \) is the initial state
- \( A \subseteq K \) is the set of accepting states, and
- \( \delta \) is the transition function from \( (K \times \Sigma) \) to \( K \)

**Configuration**: A **Configuration** of a DFSM \( M \) is an element of \( K \times \Sigma^* \). Configuration captures the two things that make a difference to \( M \)'s future behavior: i) its current state, the input that remains to be read.

The **Initial Configuration** of a DFSM \( M \), on input \( w \), is \( (s_M, w) \), where \( s_M \) is start state of \( M \)

The transition function \( \delta \) defines the operation of a DFSM \( M \) one step at a time. \( \delta \) is set of all pairs of states in \( M \) & characters in \( \Sigma \). (Current State, Current Character) \( \rightarrow \) New State

**Relation ‘yields’**: Yields-in-one-step relates configuration-1 to configuration-2 iff \( M \) can move from configuration-1, to configuration-2 in one step. Let \( c \) be any element of \( \Sigma \) and let \( w \) be any element of \( \Sigma^* \), then,

\[(q_1, cw) \rightarrow_M (q_2, w) \text{ iff } ((q_1, c), q_2) \in \delta\]

\( |-M^* \) is the reflexive, transitive closure of \( |-M \)
Complete vs Incomplete FSM

Complete FSM: A transition is defined for every possible state and every possible character in the alphabet. Note: This can cause FSM to be larger than necessary, but ALWAYS processes the entire string.

Incomplete FSM: One which defines a transition for every possible state & every possible character in the alphabet which can lead to an accepting state. Note: If no transition is defined, the string is rejected.

Computation: A Computation by M is a finite sequence of configurations $C_0, C_1, \ldots, C_n$ for some $n \geq 0$ such that:

- $C_0$ is an initial configuration,
- $C_n$ is of the form $(q, \varepsilon)$, for some state $q \in K_M$
  - $\varepsilon$ indicates empty string, entire string is processed & implies a complete DFSM
- $C_0 \Rightarrow_M C_1 \Rightarrow_M C_2 \Rightarrow_M \ldots \Rightarrow_M C_n$.

However, M Halts when the last character has to be processed or a next transition is not defined.

Acceptance / Rejection

A DFSM M, Accepts a string w iff $(s, w) \Rightarrow_M^* (q, \varepsilon)$, for some $q \in A_M$.
A DFSM M, Rejects a string w iff $(s, w) \not\Rightarrow_M^* (q, \varepsilon)$, for some $q \not\in A_M$.

The language accepted by M, denoted $L(M)$, is the set of all strings accepted by M.

Regular languages

A language is regular iff it is accepted by some DFSM. Some examples are listed below.

- $\{ w \in \{a, b\}^* \mid$ every a is immediately followed by b $\}$.
- $\{ w \in \{a, b\}^* \mid$ every a region in w is of even length $\}$
- binary strings with odd parity.

Designing Deterministic Finite State Machines

Given some language L, how should we go about designing a DFSM to accept L? In general, as in any design task. There is no magic bullet. But there are two related things that it is helpful to think about:

- Imagine any DFSM M that accepts L. As a string w is being read by M, what properties of the part of w that has been seen so far are going to have any bearing on the ultimate answer that M needs to produce? Those are the properties that M needs to record.
- If L is infinite but M has a finite number of states, strings must "cluster". In other words, multiple different strings will all drive M to the same state. Once they have done that, none of their differences matter anymore. If they've driven M to the same state, they share a fate. No matter what comes next, either all of them cause M to accept or all of them cause M to reject.

Note: Refer class notes for problems on construction of DFSM for some languages.
